

Variance Reduction for Multi-physics Analysis of Moving Systems

Chelsea D'Angelo

Preliminary Exam

Feb. 2, 2018

WISCONSIN
UNIVERSITY OF WISCONSIN-MADISON

Introduction

- Fusion Energy Systems (FES)
 - Burning plasma, D-T fusion
 - ${}^2_1\text{H} + {}^3_1\text{H} \rightarrow {}^4_2\text{He} + {}^1_0\text{n}$
- Neutrons penetrate deeply into system components, causing activation
- Radioisotopes persist long after shutdown
- Important to quantify the dose caused by decay photons

Figure : Cutaway view of ITER drawing.

- FES are designed with modular components
 - Can move during maintenance procedure
- Interested in SDR at a particular location
- SDR will change as a function of the activated component's position over time

- FES are designed with modular components

- FES are designed with modular components
 - Can move during maintenance procedure
- Interested in SDR at a particular location
- SDR will change as a function of the activated component's position over time

Optimize the calculation of the **shutdown dose rate** at a particular location as activated components are **moving** around the facility.

Direct 1-Step Method (D1S)

Rigorous 2-Step Method (R2S)

- Monte Carlo (MC) analysis of FES is:
 - Accurate for large, complex models
 - Challenging due to the highly attenuating structural materials
 - Results scored in regions that have low particle flux, have higher statistical uncertainty

Figure : Photon source in ITER tokamak building.

- Uncertainty in MC calculations:

$$\Re = \frac{\sigma_{\bar{X}}}{\bar{X}} \quad (1)$$

$$\sigma_{\bar{X}} \propto \frac{1}{\sqrt{N}}$$

- To decrease statistical uncertainty:
 - Increase number of histories, N
 - Use variance reduction (VR) techniques

- Techniques to modify particle behavior
 - **Goal:** preferentially sample events that will contribute to results of interest
- Statistical weight of particles is adjusted to keep playing a fair game
- Types
 - **Modified Sampling:** source direction and energy biasing
 - **Population Control:** geometry and energy splitting/rouletting

- Use **deterministic** estimate of the adjoint flux, Ψ^+ , to generate **Monte Carlo** VR parameters
- Adjoint flux can define the importance of regions of phase space to the detector response
- Define detector response function to be the adjoint source

Forward:

$$H\Psi(\vec{r}, E, \hat{\Omega}) = q(\vec{r}, E, \hat{\Omega}) \quad (2)$$

$$H = \hat{\Omega} \cdot \nabla + \sigma_t(\vec{r}, E) - \int_0^\infty dE' \int_{4\pi} d\Omega' \sigma_s(\vec{r}, E' \rightarrow E, \hat{\Omega}' \rightarrow \hat{\Omega})$$

Adjoint:

$$H^+\Psi^+(\vec{r}, E, \hat{\Omega}) = q^+(\vec{r}, E, \hat{\Omega}) \quad (3)$$

$$H^+ = -\hat{\Omega} \cdot \nabla + \sigma_t(\vec{r}, E) - \int_0^\infty dE' \int_{4\pi} d\Omega' \sigma_s(\vec{r}, E \rightarrow E', \hat{\Omega} \rightarrow \hat{\Omega}')$$

Consistent Adjoint Driven Importance Sampling (CADIS)

- Use the adjoint flux, Ψ^+ , to generate MC source and transport biasing parameters
- Biased source:

$$\hat{q}(\vec{r}, E, \hat{\Omega}) = \frac{\Psi^+(\vec{r}, E, \hat{\Omega}) q(\vec{r}, E, \hat{\Omega})}{R} \quad (4)$$

- Weight window lower bounds:

$$w_l(\vec{r}, E, \hat{\Omega}) = \frac{R}{\Psi^+(\vec{r}, E, \hat{\Omega})^{\left(\frac{\alpha+1}{2}\right)}} \quad (5)$$

VR for **photon** transport

- **Straightforward**
- Can use CADIS method to direct photons towards detector
 - Flux-to-dose-rate conversion factors define adjoint source

VR for **neutron** transport

- More **complicated**
- Biasing function needs to capture
 - ① Potential of regions to become activated
 - ② Potential to produce photons that will contribute to the SDR
- Can use CADIS if we can construct adjoint source that will fulfill these criteria

Multi-Step (MS)-CADIS

- VR method to optimize the initial radiation transport step of a coupled, multi-step process
 - Relies upon biasing function that represents importance of particles to final response of interest

- System of coupled, multi-physics:

$$\textit{Primary} : H\phi(u) = q(u) \quad (6)$$

$$\textit{Secondary} : L\psi(v) = b(v) \quad (7)$$

- Adjoint identities:

$$\langle \phi^+, q \rangle = \langle \phi, q^+ \rangle \quad (8)$$

$$\langle \psi^+, b \rangle = \langle \psi, b^+ \rangle \quad (9)$$

- MS-CADIS requires a representation of the relationship between primary and secondary physics:

$$b(v) = \langle \sigma_b(u, v), \phi(u) \rangle \quad (10)$$

- Response to secondary physics:

$$R_{final} = \langle \omega_R(v), \psi(v) \rangle \quad (11)$$

- Set ω_R as adjoint source and invoke adjoint identity:

$$R_{final} = \langle \omega_R, \psi \rangle = \langle b, \psi_R^+ \rangle \quad (12)$$

- Substitute Eq. 10 :

$$R_{final} = \langle \langle \sigma_b(u, v), \phi(u) \rangle, \psi_R^+(v) \rangle \quad (13)$$

- Switch the order of integration

$$R_{final} = \langle \langle \sigma_b(u, v), \psi_R^+(v) \rangle, \phi(u) \rangle \quad (14)$$

- Set response of primary physics equal to final response of the system and invoke the adjoint identity to solve for q^+ :

$$R_{final} = \langle \langle \sigma_b(u, v), \psi_R^+(v) \rangle, \phi(u) \rangle = \langle q(u), \phi_R^+(u) \rangle \quad (15)$$

- MS-CADIS adjoint primary source:

$$q^+(u) \equiv \langle \sigma_b(u, v), \psi_R^+(v) \rangle \quad (16)$$

Groupwise Transmutation (GT)-CADIS

- Implementation of MS-CADIS specifically for SDR analysis
- Provides method to calculate optimal adjoint neutron source, q_n^+ , by first calculating, T , a term that relates the neutron flux to photon source

MCNP6 Moving Objects

- Update in future version of MCNP6
- Allows movement of objects, sources, delayed particles during single simulation
- Available for native MCNP geometry descriptions (not mesh)

Mesh Coupled implementation of R2S (MCR2S)

- Capability that allows components to move before photon transport step
- Transformations are applied to copies of moving components
- Original component still in original location, set to void material

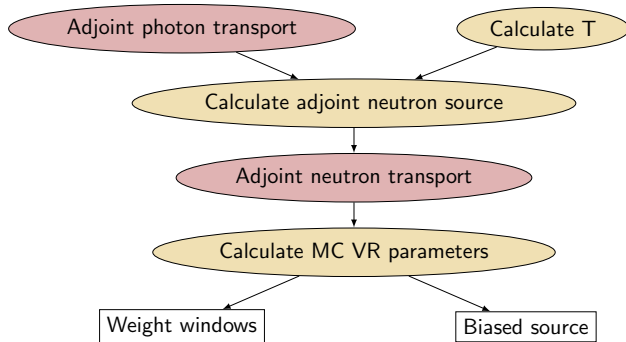

- MC method is most accurate way to obtain detailed particle flux distributions
 - Use MC codes for both neutron and photon transport steps of R2S
 - Need to use VR methods to optimize the transport calculations
- GT-CADIS, an implementation of MS-CADIS, has proven to optimize the neutron transport step of R2S
- MCNP6 and MCR2S have developed some capabilities for performing transport on moving geometries

Demonstration

- Geometry
 - Steel chamber
 - 2m x 2m x 2m central cavity
- Source
 - Volume source in central cavity
 - 13.8-14.2 MeV neutrons
- Detector
- Calculate SDR
- 2m away from chamber

- GT-CADIS workflow

Proposal

- MS-CADIS optimizes initial radiation transport step in a coupled, multi-step process
- Movement during secondary step changes the construction of the adjoint primary source

Need to derive new adjoint source

Time-integrated Adjoint Primary Source

- Geometry movement during secondary physics effects the construction of the adjoint primary source
 - Score adjoint secondary flux in discrete volume elements
 - Adjoint flux in volume element v at time t : $\psi^+(\vec{r}_v(t), t)$
 - Position of volume element v at time t : $\vec{r}_v(t)$
- Integrate over time

Time-integrated Adjoint Primary Source

- Geometry movement during secondary physics effects the construction of the adjoint primary source
 - Score adjoint secondary flux in discrete volume elements
 - Adjoint flux in volume element v at time t : $\psi^+(\vec{r}_v(t), t)$
 - Position of volume element v at time t : $\vec{r}_v(t)$
- Integrate over time

Time-integrated Adjoint Primary Source

- Geometry movement during secondary physics effects the construction of the adjoint primary source
- Score adjoint secondary flux in discrete volume elements
 - Adjoint flux in volume element v at time t : $\psi^+(\vec{r}_v(t), t)$
 - Position of volume element v at time t : $\vec{r}_v(t)$
- Integrate over time

Time-integrated Adjoint Primary Source

- Geometry movement during secondary physics effects the construction of the adjoint primary source
- Score adjoint secondary flux in discrete volume elements
 - Adjoint flux in volume element v at time t : $\psi^+(\vec{r}_v(t), t)$
 - Position of volume element v at time t : $\vec{r}_v(t)$
- Integrate over time

Time-integrated Adjoint Primary Source

- Geometry movement during secondary physics effects the construction of the adjoint primary source
- Score adjoint secondary flux in discrete volume elements
 - Adjoint flux in volume element v at time t : $\psi^+(\vec{r}_v(t), t)$
 - Position of volume element v at time t : $\vec{r}_v(t)$
- Integrate over time

Time-integrated Adjoint Primary Source

- Geometry movement during secondary physics effects the construction of the adjoint primary source
 - Score adjoint secondary flux in discrete volume elements
 - Adjoint flux in volume element v at time t : $\psi^+(\vec{r}_v(t), t)$
 - Position of volume element v at time t : $\vec{r}_v(t)$
- Integrate over time

- To apply time-integration to GT-CADIS:
 - ① Perform adjoint photon transport at each time step of geometry movement
 - ② Score adjoint photon flux in each volume element, v
 - ③ Integrate over time

- Calculate coupling term, T , for each volume element

$$T_{v,g,h} = \frac{q_{\gamma,v,h}(\phi_{n,v,g})}{\phi_{n,v,g}} \quad (17)$$

- Combine with adjoint photon flux in each volume element

$$q_{n,v,g}^+ = \frac{\sum_{t_{mov}} (\sum_h T_{v,g,h} \phi_{\gamma,v,h,t_{mov}}^+) \Delta t_{mov}}{t_{tot}} \quad (18)$$

- Perform deterministic adjoint neutron transport using the time-integrated source
- Resultant adjoint neutron flux should look something like this:

- Use this adjoint neutron flux to generate biasing parameters that will optimize the MC neutron transport step of R2S

Implementation Plan

- Generate geometry files at each time step of movement after shutdown

- Generate geometry files at each time step of movement after shutdown

- Generate geometry files at each time step of movement after shutdown

- Generate geometry files at each time step of movement after shutdown

- Generate geometry files at each time step of movement after shutdown

- Generate geometry files at each time step of movement after shutdown

- Perform adjoint photon transport at each time step

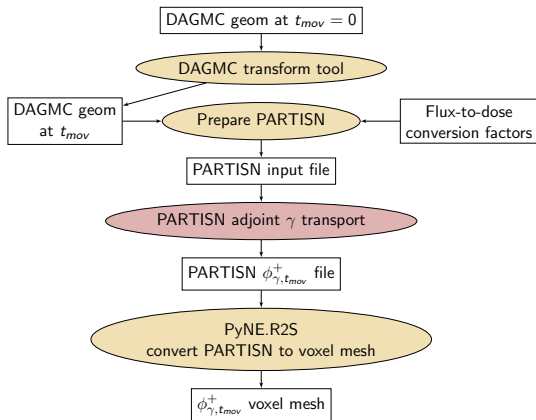

Detector

- Perform adjoint photon transport at each time step

- Perform adjoint photon transport at each time step

- Perform adjoint photon transport at each time step

- Perform adjoint photon transport at each time step

Detector

- Perform adjoint photon transport at each time step

Detector

- Map the voxel mesh to a tetrahedral mesh
- Average the adjoint photon flux calculated at each time step

- Calculate T of each voxel
- Calculate adjoint neutron source
- Perform adjoint neutron transport
- Generate biased source and weight window mesh

Experiment

- Toy problem
 - Steel chamber with moving component
 - Incrementally add optimization
 - Calculate figure of merit (FOM) to assess utility of TGT-CADIS method
- Full-scale FES demonstration

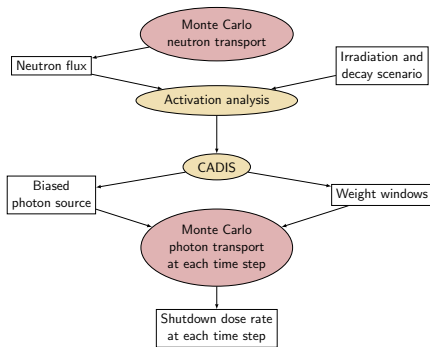

Experimental Steps:

1 No VR

Experimental Steps:

- 1 No VR
- 2 Photon VR:
CADIS

Experimental Steps:

- 1 No VR
- 2 Photon VR:
CADIS
- 3 Neutron and
Photon VR:
TGT-CADIS

Progress

- Tools to update position of geometry based on user-defined motion data
 - ① Production of step-wise geometry files
 - ② DAGMC update to facilitate on-the-fly geometry transformations
- Motion data:
 - Time-dependent translation or rotation vector, total length of time, number or desired time steps
 - Relocation transform
- Common functionality:
 - Read tag data that specifies type of transformation
 - Identify starting position of each component
 - Update position according to transformation

Conclusions

- Photon transport occurs much faster than geometry movement \therefore reasonable to do quasi-static simulation
- Period of geometry movement is short enough that the photon source will not change appreciably \therefore can use same photon source for all MC calculations

- Depending on complexity of model and fidelity of time resolution, can amass large number of CAD geometry files, volume mesh tally files
- Need to optimize this workflow in order to keep file storage at minimum

- Accurate quantification of the SDR during maintenance procedures is crucial to the design and operation of FES
- GT-CADIS has proven to accurately quantify the SDR in static FES
- TGT-CADIS aims to provide the capabilities necessary to calculate the SDR at various time points during operations that involve activated components moving around the facility
